NB Population Genomic Analysis on Haplotig Masked Outlier SNPs

Amy Zyck

2/23/2021

Population analyses on Outlier SNP (Haplotig) dataset

I first created a new directory OutlierHap within PATH: /home/azyck/NB_capture/NB_ddhaplo/NB_PopGenHap. I linked outlierlocihap.recode.vcf to this working directory. The RMarkdown file should be saved in this same working directory.

Outlier SNPs

Loading required package: bigstatsr

Making files

Make genind object

outlierlocihap.recode.vcf contains outlier SNPs (putatively under selection) for populations PVD, GB, BIS, and NAR called from reads aligned to the Eastern Oyster haplotig masked genome. Steps for generating this VCF file are located in EecSeq_Cvirginica_dDocent.md and EecSeq_Cvirginica_Filtering.md. Population NIN was removed from the VCF file following steps in EecSeq_Cvirginica_OutlierDetection.md.

strata contains population, environmental, and library information for each sample - can be accessed here.

```
my_vcf <- read.vcfR("outlierlocihap.recode.vcf")</pre>

Estimating effective migration surfaces (EEMS)

The program runeems_snps implements the EEMS method for analyzing spatial population structure. This version uses the pairwise genetic dissimilarity matrix computed from SNP data.

Here is the code used to run runeems_snps in both RStudio and command-line. Detailed steps for running this program can be accessed here. Input files are created in RStudio or manually (see below) and saved to the directory where runeems_snps will be run. The program is then run in the command-line. The outputs are then plotted in RStudio.

runeems_snps requires three data input files that have the same file name but different extension. The description below assumes that datapath is the full path + the file name (but without the extension).

1. datapath.diffs

datapath.diffs is the matrix of average pairwise genetic dissimilarities. This can be computed with bed2diffs from genetic data in plink binary format.

The dissimilarity matrix is nonnegative, symmetric, with 0s on the main diagonal. These conditions are necessary but not sufficient for diffs to be a valid dissimilarity matrix. Mathematically, diffs should be conditionally negative definite.

Steps for generating datapath.diffs are completed in RStudio.

```
# V1 methtod to get diffs matrix, preferred
bed2diffs_v1 <- function(Geno) {
   nIndiv <- nrow(Geno)
   nSites <- ncol(Geno)
   Diffs <- matrix(0, nIndiv, nIndiv)</pre>
```

```
for (i in seq(nIndiv - 1)) {
    for (j in seq(i + 1, nIndiv)) {
      x <- Geno[i, ]
      y <- Geno[j, ]</pre>
      Diffs[i, j] \leftarrow mean((x - y)^2, na.rm = TRUE)
      Diffs[j, i] <- Diffs[i, j]</pre>
    }
  }
 Diffs
}
# V2 method to get .diffs matrix, only if V1 doesn't work
bed2diffs v2 <- function(Geno) {</pre>
 nIndiv <- nrow(Geno)
 nSites <- ncol(Geno)
 Miss <- is.na(Geno)
  ## Impute NAs with the column means (= twice the allele frequencies)
 Mean <- matrix(colMeans(Geno, na.rm = TRUE), ## a row of means
                  nrow = nIndiv, ncol = nSites, byrow = TRUE) ## a matrix with nIndiv identical rows of
  Mean[Miss == 0] <- 0 ## Set the means that correspond to observed genotypes to 0
  Geno[Miss == 1] <- 0 ## Set the missing genotypes to 0 (used to be NA)
  Geno <- Geno + Mean
  ## Compute similarities
  Sim <- Geno %*% t(Geno) / nSites
  SelfSim <- diag(Sim) ## self-similarities</pre>
  vector1s <- rep(1, nIndiv) ## vector of 1s
  ## This chunk generates a `diffs` matrix
  Diffs <- SelfSim %*% t(vector1s) + vector1s %*% t(SelfSim) - 2 * Sim
  Diffs
}
geno <- stratted.filt@tab</pre>
# Get rid of non-biallelic loci
multi.loci <- names(which(stratted.filt@loc.n.all != 2))</pre>
multi.cols <- which(grepl(paste0("^", multi.loci, "\\.\d+$", collapse = "|"), colnames(geno)))</pre>
if (length(multi.cols)) geno <- geno[, - multi.cols]</pre>
nloci <- dim(geno)[2] / 2</pre>
dim(geno)
## [1]
stopifnot(identical(stratted.filt@type, 'codom'))
# bed2diffs functions
diffs.v1 <- bed2diffs_v1(geno)</pre>
diffs.v2 <- bed2diffs_v2(geno)
# Round to 6 digits
diffs.v1 <- round(diffs.v1, digits = 6)
diffs.v2 <- round(diffs.v2, digits = 6)</pre>
```

Check that the dissimilarity matrix has one positive eigenvalue and nIndiv-1 negative eigenvalues, as required by a full-rank Euclidean distance matrix. If the V1 method does not make a Euclidean matrix, you must use V2.

2. datapath.coord

datapath.coord are the sample coordinates, two coordinates per sample, one sample per line. The sampling locations should be given in the same order as the rows and columns of the dissimilarity matrix.

Steps for generating datapath.coord are completed in RStudio.

```
## Get gps coordinates from previously created info matrix
xOR.info <- dplyr::filter(info)
gps_matrix <- select(xOR.info,c("Longitude","Latitude"))

#write .coord file
write.table(gps_matrix, paste(suf,".v1.coord",sep=""),col.names = FALSE, row.names = FALSE,quote = FALSE</pre>
```

3. datapath.outer

datapath.outer are the habitat coordinates, as a sequence of vertices that form a closed polygon. The habitat vertices should be listed counterclockwise and the first vertex should also be the last vertex, so that the outline is a closed ring. Otherwise, EEMS attempts to "correct" the polygon and prints a warning message.

datapath.outer is created manually in Excel, based on site coordinates gathered from Google Maps, copied into terminal using nano, and saved as the file with the appropriate extension.

**runeems_snps is then run in command-line following the steps documented in NB_EEMS_OutlierHap.md

Back in RStudio to plot runeems_snps outputs

Loading rworldxtra (required by add.map)

Seascape Redundancy Analysis

This code follows that documented by Tom Jenkins.

Prepare genetic data for redundancy analysis.

Notes before execution:

- 1. Make sure all required R packages are installed.
- 2. Set working directory to the location of this R script.

```
# Load packages
library(adegenet)
library(poppr)

## Registered S3 method overwritten by 'pegas':
## method from

I also prepared spatial data for the redundancy analysis which is documented here.

Allele frequency, environmental, and spatial csv files are saved to your working directory and must be imported into the Rscript to run the redundancy analysis. Documentation of the RDA can be accessed here.

RDA and pRDA output plots can be viewed here.
